FEASIBILITY OF A RIVER PORT GRAIN ELEVATOR AT SAVANNA, ILLINOIS. By Clifford D. Jones, Jr. and Bruce L. Brooks; Natural Resource Economics Division; Economics, Statistics, and Cooperatives Service; U.S. Department of Agriculture; Washington, D.C., 20250 and Department of Agricultural Economics, University of Illinois, Urbana-Champaign, Illinois, respectively; May 1980.

#### ABSTRACT

This feasibility study of a proposed grain elevator focuses on an 11-county area covering parts of the Mississippi Valley located in northwest Illinois, northeast Iowa, and southwest Wisconsin. Projected estimates of production and exportable surpluses of corn, oats, and soybeans are used involving grain movements based on primary and secondary data from country elevators and trucker-dealers. Potential yearly grain flows to the proposed million-bushel river terminal are estimated at 9 to 14 million bushels for 1980, yielding variable investment returns. Estimated yields are 5, 10, and 16 percent when annual grain flows through the river terminal are 9, 11, and 14 million bushels, respectively.

Key words: River grain terminals, Feasibility analysis, Cost/return, Grain marketing patterns, Mississippi River grain movement, Illinois, Iowa, Wisconsin.

#### ACKNOWLEDGEMENTS

Many individuals in the Soil Conservation Service (SCS); Economics, Statistics, and Cooperatives Service (ESCS); University of Illinois; and the USDA State Statistical Offices of Illinois, Iowa, and Wisconsin contributed to the development of the initial questionnaire and provided secondary data.

The authors are indebted to the local RC&D personnel who aided in conducting the survey of country elevators as well as to the many country elevator operators and trucker grain dealers who cooperated in the survey. Special appreciation is extended to John Miner and Thomas H. Dempster, Resource Conservation and Development Branch, SCS for their help during the formulation, development and distribution of this report. Robert B. McKusick contributed greatly to the initial development and execution of the study. The authors also wish to thank Dwight Gadsby who aided in the editorial and review process of this study. Finally, special thanks is extended to Mrs. Barbara Simmons who processed the manuscript through several drafts.

This study was funded by the Soil Conservation Service under authority of the RC&D Program (P.L. 87-703, Section 102 of the Food and Agriculture Act of 1962) through transfer of RC&D funds to the Economics, Statistics, and Cooperatives Service.

## EXECUTIVE SUMMARY

### THE FEASIBILITY OF A RIVER PORT GRAIN ELEVATOR AT SAVANNA, ILLINOIS

by

Clifford D. Jones, Jr., and  
Bruce L. Brooks 1/

The Blackhawk Hills Resource Conservation and Development Project proposed a feasibility study of a river port grain terminal at Savanna, Illinois as an RC&D activity. 2/ The goal of the project leadership was to increase returns to the natural resources of the Blackhawk Hills RC&D Project Area.

Data used in this study were obtained from a survey of country elevators and trucker grain dealers in the region. Other supporting data were obtained from sources such as university research findings and census information. Study data were integrated to answer the questions posed by the leaders of the Blackhawk Hills RC&D Project, i.e., (1) how much grain would flow through a river terminal at Savanna and, (2) would it be a sufficient quantity to make the terminal an economically feasible operation? Research results were:

- . Grain production for the area is trending upward but at a lower rate than in the early and middle seventies.
- . There is a sufficient volume of grain production and exportable surplus to support a river grain terminal marketing facility at Savanna, Illinois.

1/ Clifford D. Jones, Jr., Agricultural Economist, ESCS, U.S. Department of Agriculture. Bruce L. Brooks, Professor of Agricultural Economics, University of Illinois, Urbana-Champaign.

2/ This study was funded through transfer funds to the Economics, Statistics, and Cooperatives Service under a memorandum of understanding with the Soil Conservation Service.

- . Based on savings in highway transport costs, researchers concluded that 9 to 14 million bushels of grain would move through the hypothetical terminal in 1980. It is conservatively estimated that the amount of grain that would move through the terminal over the next 15 years would average about 14 million bushels annually.
- . It was concluded, based on assumptions regarding the terminal's construction and operation costs, the investment yield could range from 5 to 16 percent during the first year of operation, given three estimated levels of grain business and attendant assumptions.

Major conclusions derived from this study rested on a number of assumptions. A primary study assumption was that coarse grain consumption per animal unit in the study area will remain the same for all livestock classes. Another key assumption was that the international demand for grain would continue to grow. Corn would be the major grain for export with an estimated average increase in demand for transportation service (exportable surplus grain) of 2.4 percent per year for the period 1975-1995.

Study results based on highway transport costs alone, indicate that a grain terminal at Savanna might do the following volume of business over the next 15 years: 12 to 15 million bushels by 1985; 15 to 18 million bushels by 1990; and 17 to 20 million bushels by 1995.

Results of the cost/return analysis indicated that an investment in the proposed terminal at Savanna could yield a return ranging from 5 to 16 percent during the first year's operation. The 5 percent rate of return reflects conservative assumptions relative to the first year's business of the proposed terminal. Estimated returns could be increased, however, depending on the management of the terminal, country elevators and farmers' reaction toward the Savanna grain facility, and construction economy and site acquisition costs.

THE FEASIBILITY OF A RIVER PORT GRAIN  
ELEVATOR AT SAVANNA, ILLINOIS

by

Clifford D. Jones, Jr., and  
Bruce L. Brooks 1/

INTRODUCTION

The production and marketing of grain is an important part of the total economic well-being of the producers and marketers of grain in this area in northwest Illinois. Efforts to increase the efficiency of the system now in use are justified for a number of reasons including: (1) the volume of grain that must find a market off the farms in the area, and (2) the need to continually strive for improved efficiency in the existing system.

This report was prepared by the Economics, Statistics, and Cooperatives Service (ESCS) for the Blackhawk Hills RC&D Council for use in evaluating the feasibility of a proposed grain elevator to be located on the Mississippi River at Savanna, Illinois. 2/

Directors of the Blackhawk Hills Project believe a grain port facility on the Mississippi River near Savanna, Illinois would improve the efficiency of grain marketing in their area. According to an earlier assessment of the Blackhawk Hills grain transportation problem, local farm leaders and grain dealers have been concerned for several years about adequacy of transportation

---

1/ Clifford D. Jones, Jr., Agricultural Economist, ESCS, U.S. Department of Agriculture. Bruce L. Brooks, Professor of Agricultural Economics, University of Illinois, Urbana-Champaign.

2/ The Blackhawk Hills RC&D Project was organized as part of the Resource Conservation and Development (RC&D) Program Authorized by P.L. 87-703, Section 102 of the Food and Agriculture Act of 1962. One of the RC&D program's objectives is to encourage development in rural areas through improved use of natural resources. The program is operated by local people who receive assistance from authorized Federal agencies. The ESCS participates in the program under an agreement with the Soil Conservation Service (SCS) which is the lead agency in administering the program. The Blackhawk Hills RC&D area includes Jo Daviess, Stephenson, Carroll, Ogle, Whiteside, and Lee Counties in northwest Illinois. However, the grain port study area, identified in table 1, page 12, includes only 4 of these counties plus 7 other counties in Illinois, Iowa and Wisconsin.

to serve the area's expanding commercial grain trade. Formerly, the Blackhawk Hills area was a deficit feed grain area. Grain moved into rather than out of the area (13). <sup>3/</sup> However, in recent years, grain production has been increasing more rapidly than feeding requirements. Substantial amounts of grain are now available for shipment out of the area (tables 4, 5, and 6). It is estimated that about 60 percent of the feed grain produced in the area is fed to livestock and about 40 percent is exported. <sup>4/</sup> Much of the surplus grain is moved by truck to grain terminals on the Illinois and Mississippi Rivers where it is loaded onto barges and shipped to the Gulf for export to foreign markets.

During the period 1963-73, U.S. grain exports through Gulf ports increased almost 250 percent, exports of grain through Great Lakes ports showed only a modest increase, and exports through Atlantic ports declined (14). This suggests that the predominant expansion in U.S. grain export trade affecting midwest farmers will be through Gulf ports. The U.S. export market for feed grain and soybeans will likely play a major role in the success of a river terminal at Savanna, since barge activity in the midwest grain area is directly linked with Gulf ports and export trade.

In 1970, 14 midwestern grain marketing and farm supply cooperatives shipped two and one-half million tons of grain to the Gulf by barge. Louisiana Gulf ports were the major destination of these southbound barge shipments, accounting for 99.6 percent of the total. Louisiana ports also received 64 percent of the 14 cooperatives' grain shipments by rail (14). Between 1970 and 1974, midwest

---

<sup>3/</sup> Underscored numerals in parenthesis refer to items in the Bibliography.

<sup>4/</sup> Estimated percentages based on historic corn disposition statistics from publications of Illinois Cooperative Crop Reporting Service (8). In this report "grain for export" or "exportable surplus grain" is defined as grain produced in the 11-county study area in excess of local feed, seed, and processing requirements. "Exportable surplus" is the grain that moves out of the study area via truck, barge or rail to other destinations in Illinois, to other States, or into the world market.

barge shipments of corn and soybeans down the Mississippi and Illinois Rivers to the Baton Rouge-New Orleans, Louisiana area increased by 79 percent and 18 percent, respectively (6).

Based on these favorable trends for barge transportation and related businesses, it would appear that future prospects are bright for river grain handling firms in the midwest. However, the general increase in barge transportation of grain is no reliable basis for assuming that a new firm at Savanna could capture a share of this business.

### Study Objectives

Key questions facing the investors/managers of a river grain terminal at Savanna are:

- (1) How much grain will flow through the terminal?
- (2) Will the terminal be a profitable operation?

Of course, answers to these questions depend to a large extent on the personal acumen and skills of the management of the terminal. This cannot be readily assessed and was not an objective of this study. Other factors which can be assessed, and which will affect the success of a grain terminal at Savanna form the study objectives: (1) how much grain is produced in the area, (2) how much is available for export from the area, (3) how much of the exportable surplus can be expected to move through a terminal at Savanna, and (4) what is the likely cost/revenue structure of a Savanna grain terminal?

### Analytical Approach and Methodology

These objective factors were assessed and analyzed for an 11-county area around Savanna, Illinois covering parts of Illinois, Iowa, and Wisconsin. The counties are identified in table 1. The selected counties were designated as the potential service area of the proposed terminal in consideration of distance from Savanna and locations of other existing river grain terminals.

The analytical approach used in appraising the above factors was as follows:

- (1) Estimate 1975, 1980, 1985, 1990, and 1995 production in the 11-county area for the major grains (corn, oats, and soybeans), using historical production trends for each crop.
- (2) Estimate 1975, 1980, 1985, 1990, and 1996 local use of corn, oats, and soybeans, using local livestock and poultry feed requirements and local processing of any of the commodities as an indication of local use, i.e., grain used or consumed in the 11-county study area.
- (3) Estimate 1975, 1980, 1985, 1990, and 1995 exportable surplus production of corn, oats, and soybeans in the 11-county area by deducing local use of each commodity from estimated local production.
- (4) Estimate the amount of exportable surplus grain that would likely move through a river grain terminal at Savanna. Use current destinations of surplus grain, mode of transport, transport costs, and distance hauled as determining factors in the flow of grain.

A survey of country elevators and trucker-dealers was conducted to determine mode of transportation, transport costs, and to verify the marketing patterns of grain produced in the 11-county area. Additional barging costs resulting from loading grain at a Savanna port rather than alternative down river ports serving the designated study area were considered insignificant and dropped from explicit consideration.

- (5) Estimate the cost/revenue structure of a hypothetical river grain terminal at Savanna. Assume three alternative model river grain elevators of specified capacities and develop cost data on each model. Develop a cost/return analysis on one model based on a conservative estimate of the volume of grain that a terminal at Savanna might expect to handle during the first year of operation.

Use survey data collected from country elevators and trucker dealers, grain terminal operating costs estimated in other studies, "rule of thumb" construction cost estimates cited by grain elevator operators and those who construct grain handling facilities and assumed margins as guideline information in developing the cost/return analysis.

Grain production was estimated for each county in the study area for the years 1965-75 and projected at 5-year intervals to 1980, 1985, 1990, and 1995 using secondary data. 5/ The data used in making these estimates came from several sources, including publications of State Universities, State Departments of Agriculture, the U.S. Department of Agriculture, and the U.S. Censuses of Agriculture (1, 3, 10, 18, 19, 22, 23). The projected estimates were developed using linear regression analysis of annual historical corn, oats, and soybean production data for each county. Adjustments were made in linear projections of individual counties that showed strong deviations from indicated trends in the study area using data from other studies (1, 3, 22).

Local livestock and poultry consumption of corn and oats was determined by estimating the annual feed use of each grain for 1975, 1980, 1985, 1990, and 1995 based on existing secondary data of annual livestock feed usage in study area counties (3), and where livestock usage was not available, by estimating current and future livestock and poultry numbers for each county and multiplying estimated numbers by annual feed ration rates for each class of livestock. Projections of livestock numbers were based on trend analysis of annual historical data in State and USDA publications (1, 3, 9, 10, 23). Annual feeding rates of each grain by class of livestock and poultry were obtained from other studies for Iowa and Illinois (1, 3).

---

5/ Grain production estimates include only corn and oats harvested for grain and soybeans for beans.

The amount of soybeans used on farms is normally insignificant. Therefore, only a small amount was estimated to be consumed locally, based on reported onfarm usage in Illinois and Iowa (1, 3, 8).

Exportable surplus grain is defined as the excess of local production over local use, or more precisely, the residual after subtracting estimated local feed, seed, and processing use from estimated production. The difference is assumed to be exported from the study area. Exportable surplus grain was estimated for each county in the study area for 1975, 1980, 1985, 1990, and 1995 by computing the difference between estimates of production and use in each county for the specified years.

It was assumed that the amount of exportable surplus grain that would likely move through a river grain terminal at Savanna would be related to the cost of transporting the grain from farms and country elevators to Savanna, as opposed to the cost of transporting it to other alternative grain terminals serving the study area.

According to two recent studies in Illinois, grain sold from Illinois farms moves primarily through four types of grain handling firms: (1) country elevators, (2) terminal and export elevators, (3) feed mills and manufacturers, and (4) grain processors. Most of the grain sold from farms in Illinois is first handled by country elevators, with minor quantities going directly to terminal elevators, local feed manufacturers, and processors. In 1970, 89 percent of the corn and 90 percent of the soybeans sold from Illinois farms moved through country elevators. This pattern had not changed appreciably in 1973, when it was estimated that country elevators received 92 percent of the corn and 94 percent of the soybeans sold by Illinois farmers. From the country elevator, grain moves to Illinois processors, terminal and export elevators, destinations in other States including feed and processing firms in the Southeast, and back to local farmers for feed (2, 7).

It was assumed that the relationship of the country elevator in the grain marketing chain in Illinois would hold for the study area, and that country elevators in the study area would be the most reliable source of prevailing grain flows, transportation mode, and hauling costs. Therefore, country elevators were surveyed to obtain the basic data used in estimating the amount of surplus grain and soybeans that could be economically delivered to a Savanna terminal. Mode of grain transport, costs of transporting grains and the volume of grain moving from farms and country elevators to the different terminals inside and outside the study area were obtained by the use of a mail, telephone, and personal interview survey of 76 country elevators and trucker-dealers located in the 11-county study area.

All of the 76 elevators and trucker-dealers were first contacted by mail. Those who did not respond were then visited personally or via telephone. Response to the questionnaire was received from 24 country elevators and 6 trucker-dealers in Illinois, 12 country elevators in Iowa, and 3 country elevators in Wisconsin. For the whole study area, this amounted to a 59.2 percent response rate.

Data from the survey of country elevators and trucker-dealers were used to determine the flow or destination of the exportable surplus grain and the mode and cost of transportation. Survey data on cost and distance hauled were used in regressing cents per bushel on miles hauled to each terminal for corn and soybeans. The resulting regression coefficients from this analysis were used to compute the transportation costs for hauling corn, soybeans, and oats to the terminals now used and to a proposed facility at Savanna by the country elevators and trucker-dealers surveyed. The most direct road mileages to each of the terminals now used by the elevators and trucker-dealers were taken from State highway maps. The mileage, from each

of these elevators and from the location of each trucker-dealer to Savanna, was obtained in the same manner. The difference in mileages to Savanna and to the terminal used were then computed. This figure was multiplied by the cost per bushel-mile regression coefficient to determine the difference in cost of transporting grain from any facility to any terminal used and the cost of transporting the same grain to a Savanna facility. If the distance was less to Savanna than to the terminal to which the grain was transported, then the cost of transporting the grain to Savanna was less. Given lower transport costs, it was then assumed the grain would flow to Savanna, other things being equal.

A formulation of the above computational steps used in deriving estimated grain transportation cost savings follows:

Transportation savings =  $[(x-y)z]v$ , where

x = Distance to alternative terminal

y = Distance to Savanna ( $y < x$ )

z = Cost per bushel-mile for transporting grain (which is .096 cents for corn and oats and .086 cents for soybeans, based on results of the country elevator and trucker-dealer survey)

v = Volume of grain transported to Savanna

The cost/return analysis of a river grain terminal at Savanna was developed using mostly secondary data from other studies (5, 6, 12, 14, 15, 16, 17), supplemented with data obtained from the country elevator survey, and personal interviews with grain elevator construction contractors and grain elevator operators. Annual operating-cost data were developed for three different sizes of river grain terminals which are capable of handling the amounts of grain that would likely be moving through a Savanna terminal (table 10). A cost/return analysis was developed for one alternative river

grain terminal model, assuming that a Savanna grain facility could attract between 7 and 9 million bushels of grain from the study area during the first year of operation. Cost data were developed for the same model operating at different volume levels to show how costs per bushel vary depending upon the amount of grain handled.

Other factors affecting the financial feasibility of a river grain terminal in the study area were examined including the export trade prospects for midwest grain farmers and grain handlers. Also, the effect of waterway user charges on barge traffic is briefly discussed and analyzed using information from a simulated case study for central Illinois (4).

#### General Assumptions

The following general assumptions are made in relation to this study:

1. General economic conditions now prevailing in the United States and the world will continue.
2. The export demand for U.S. grains and soybeans will continue at about the present level.
3. The cropping patterns of grain crops grown in the study area will remain essentially the same as they are at present.
4. The coarse grain consumption per animal unit in the study area will remain the same as it is at the present time for all livestock classes.
5. Trends in the total volume of each feed grain fed to livestock in the study area will continue to move in the same direction as in the past.
6. The present level of technology exhibited in grain handling, transportation, and storage in the study area will not markedly change in the foreseeable future.

7. The use of coarse grains and soybeans in the United States for food and industrial purposes will remain about the same as it is at the present time.

#### Limitations

In this study, transportation costs are the only costs considered in determining quantity of grain flow to the different river facilities. The researchers recognize that the kinds and quality of other services are often important in determining the facility to which grain will flow. In this study, these are ignored.

## GRAIN PRODUCTION

The historic and projected production of each of the three major grains produced in the grain port study area is shown in tables 1, 2, and 3. Table 1 clearly shows an upward trend in corn production averaging about 4.5 percent per year over the 11-year period from 1965-75. Projected to 1995, corn production increases 87 percent over 1965. This is an average annual increase in corn production of about 2.8 percent over a 31-year period. When compared to the 4.5 percent average annual increase for the period 1965 through 1975, this estimated annual increase appears to be conservative, but perhaps more realistic than using the very large increases attained in a number of recent years.

Soybean production also shows a distinct upward trend (table 2). The production of soybeans in the study area rose an average of about 14.6 percent annually from 1965 to 1975. The projected production over the 31-year period from 1965 to 1995 also shows a marked increase, averaging about 12.0 percent annually for the 31 years. However, this rate of increase is not expected to continue at the same level between 1975 and 1995. During the 20-year period the average annual rate of increase in soybean production is estimated to drop to 4 percent.

Oat production shows a historic downward trend over the 11-year period, 1965-75, with an average annual decline in production of about 3.5 percent (table 3). Projected production of oats to 1995 shows a reduction in the rate of the downward trend with an average annual decline of about 1.8 percent for the 31-year period. Oat production is projected to decline at a rate of about 1.3 percent per year between 1975 and 1995.

No production data was developed for wheat. Although some wheat is grown in the area, it is considered an insignificant grain crop relative to its importance to a river grain terminal at Savanna. The grain marketing

Source: Historical estimates came from a series of State Agricultural Statistical publications for Illinois, Iowa, and Wisconsin (9, 10, 23). Projected estimates were developed using linear regression analysis of annual historical production data for each county. Some linear projections were adjusted based on indicated trends in other studies for study area counties and for areas which contained study area counties (1, 3, 22).

district in northern Illinois, which includes the Illinois portion of the grain port study area, is a deficit wheat area—more wheat is fed to livestock than produced (3).

The total estimated volume of grain produced in the 11-county area in 1975 was 136,320,700 bushels of corn; 7,147,300 bushels of soybeans; and 14,927,400 bushels of oats, which is a total production of all three grains of 158,395,400 bushels. When the total production of these three grains is projected to 1995, the total is 193,539,200 bushels, an increase of 22 percent over 1975 production of these three grains in the 11-county area.

These county production data show that there is now, and is projected to be, a sizeable volume of grain to be used in local feeding and processing or marketed from the area. About 47 to 51 percent of the grain now comes, and is projected to come, from five Illinois counties, about 27-35 percent from three Iowa counties, and about 14-24 percent from three Wisconsin counties. About 86 percent of the grain that is now produced in the 11-county area is produced in Illinois and Iowa. Projected estimates of grain production are believed to be somewhat conservative. Actual production in future years could average 7 to 10 percent higher than projected levels if recent increases in production are maintained.

Much of the grain that is produced never moves beyond the local area where it is grown. It is either fed on the farm where it is produced, moved short distances to other farms where it is fed to livestock, or moved to small feed mills and then returned to the farm. Some of the grain moves to country elevators and is returned direct to the area farms or to local feed mills and then back to the farms. Grain treated in this manner is not considered to be commercial grain in this study. Only the grain that moves to country elevators or terminals for further transshipment by truck, barge, or

rail is of concern in this study. This grain, defined as exportable surplus grain, is that amount of local production in excess of local requirements for feed and seed.

## EXPORTABLE SURPLUS GRAIN

The exportable surplus of corn, oats, and soybeans in the 11-county study area is estimated for 1975 and projected at 5-year intervals from 1980 to 1995, by counties and by States (tables 4, 5, and 6).

The estimated exportable surplus of corn, oats, and soybeans combined from Illinois counties alone was slightly over 44 million bushels in 1975. This surplus production consisted of about 37 million bushels of corn; 2.5 million bushels of oats, and 4.5 million bushels of soybeans. The exportable surplus estimates of corn, oats, and soybeans in the Iowa portion of the study area in 1975 were 14.2 million bushels of corn, slightly over 1.0 million bushels of oats, and about 2.3 million bushels of soybeans. Exportable surplus estimates for the Wisconsin portion of the study area in 1975 was just over 7.0 million bushels of corn, about 0.5 million bushels of oats, and about 0.2 million bushels of soybean.

A continual upward trend in exportable surplus of corn is estimated for the study area and each county within it. For the total area, corn surplus is projected to increase about 49 percent between 1975 and 1995. This is an average annual increment of about 2.4 percent over the 20-year period (table 4). The exportable surplus of soybeans in the study area is projected to rise during each 5-year period from 1975 to 1995. The projected annual increase in exportable surplus averages about 4.0 percent, or 286,000 bushels per year (table 5). Projected exportable surplus of oats shows a decline of about 19.3 percent between 1975 and 1995. The decline averages almost 1.0 percent a year starting from 1975, or about 39,500 bushels annually (table 6).

The total amount of exportable surplus grain in the study area available to move into commercial channels by country elevators and terminals is projected to increase at the rate of 2.4 percent per year between 1975 and 1995. The increases in exportable surpluses of corn and soybeans are somewhat

export out of area, production less local consumption.

offset by the decline in oats. In total, grain available for export from the 11-county area is expected to increase from about 69 million bushels in 1975 to about 103 million bushels in 1995.

## ESTIMATED VOLUME OF GRAIN THAT WOULD MOVE TO A SAVANNA TERMINAL

The main problem in this study was to determine if there is now and will be in the future a sufficient volume of exportable surplus grain in the grain port service area that can be economically delivered to a river terminal at Savanna, Illinois to warrant investment in grain facilities at Savanna. The basis for determination of whether the grain can be delivered is based on whether the per bushel-mile cost of delivery to Savanna is lower than it is to the terminal or terminals to which the grain was moved during the 1975-76 crop year. Explicit consideration was given only to trucking costs.

### Total and Commercial Grain Flows in Study Area

Current grain flows, mode of transport, and transportation costs of moving grain from farms and country elevators in the study area to other destinations were obtained from data acquired in a sample survey of 76 country elevators and trucker-dealers operating in the study area. Response from 45 country elevators and trucker-dealers showed that, of the 28.5 million bushels of grain handled, they moved about 24.6 million bushels of corn, oats, and soybeans into commercial channels during the 1975-76 marketing year (table 7). About 86 percent of the total volume handled went into commercial outlets and left the area, and approximately 14 percent was retained in the area for feed and other local uses.

The total volume of commercial sales by the respondent elevator and trucker grain dealers accounted for about 35.5 percent of the total estimated surplus surplus of corn, oats, and soybeans in 1975. The remaining exportable surplus was handled by elevators and trucker-dealers who were not included in the survey or who did not respond to the survey and by farmers who hauled their grain direct to river terminals and other outlets, by-passing country elevators. Survey response indicated that the farther removed country elevators surveyed were from Savanna, the less inclined they were to respond to

Table 7 --Volume and percentage of corn, soybeans, and oats marketed by 45 country elevators and trucker-dealers that remain in local area and move into commercial channels, grain port study area, by States, 1975-76 <sup>1/</sup>

<sup>1/</sup> Marketing year for each grain is the one used by ESCS, USDA.

the survey questionnaire. Therefore, it can be reasonably assumed that because of distance these elevators would not likely use a Savanna facility, other things being equal. Consequently, the the amount of grain for which a river facility at Savanna might compete is probably in the neighborhood of that amount indicated going into commercial channels based on the survey response, or roughly 24.6 million bushels of all three commodities combined.

Most of the commercial grain sales were to river terminals on the Mississippi and Illinois Rivers. Very few oats went to river terminals. The predominant mode of transportation to river terminals was by trucks hauling 500 bushels or more. The trucking costs from country elevators and farms to river terminals were estimated at 0.096 cents per bushel-mile for corn and oats and 0.086 cents per bushel-mile for soybeans.

#### Optimistic Estimates of Grain Flows Through a Savanna Terminal

Based on transportation costs and the marketing patterns of the study area surplus grain handled by the respondent elevator and trucker-dealers, an estimated 20.5 million bushels of grain would have moved through a facility at Savanna in 1975, and 22.2 million by 1980 (tables 8 and 9).

The estimated savings in transportation costs to country grain shippers (country elevator and trucker-dealers responding to the grain flow/transportation cost survey) by moving their grain to a Savanna facility rather than to the destination used in 1975-76 was estimated at about \$594,000 (table 8). Because most of the grain originated in Illinois, the greatest benefit due to lower transportation costs would accrue to Illinois grain dealers and farmers. It is estimated they could have realized about \$559,000 in highway transportation cost reductions in 1975-76 by shipping grain through a Savanna terminal.

1/ Based on trucking costs alone, other factors influencing grain flow to terminals assumed to be equal. Estimates for projected years 1980-1995 are based on assumed continued relationship between exportable surplus grain available for shipment and that portion moving to Savanna in 1975-76 as established via the country elevator survey. 1975 estimates are from table 8.

2/ Estimates are based on analysis of survey results, moving grain to nearest terminal or via the least transportation cost route. They are considered to be maximum levels because they include movement of grain via Savanna regardless of the magnitude of savings in transportation costs--in many instances grain was routed through Savanna when savings were only marginal.

3/ Estimate No. 2 is a more realistic estimate than No. 1 and reflects downward adjustments in the first level maximum estimates to account for that grain which was estimated to move to Savanna when savings in transportation costs were marginal. Includes only grain produced in Illinois counties of the study area.

4/ Estimate No. 3 is the most conservative of all three estimates. It is based on an analysis that included only that volume of grain handled by Illinois country elevators and trucker-dealers who answered "yes" to the survey question: "Would you use a river elevator in Savanna?" All "yes" responses were within 50 miles of Savanna and showed grain going to Savanna due to lower trucking costs (savings of 2 cents or more per bushel). This analysis also excluded corn, oats, and soybeans that moved to destinations other than river terminals, such as Illinois and Iowa processing plants.

### Conservative Estimates of Grain Flows Through a Savanna Terminal

All of the elevators surveyed were asked if they would ship to a river terminal elevator at Savanna if one were built. The amount of grain reported shipped to river terminals by the Illinois respondents answering "yes" to this question was about 10.3 million bushels of corn, about 0.8 million bushels of soybeans and and no significant quantity of oats (Column 1, estimate No. 3, table 9). Several of the respondents expressed concern about poor road conditions and the detrimental effect that these could have on their equipment. Three of the 24 Illinois respondents said "no" because of the inadequacy of roads, weight limits on bridges, additional time and the equipment required. Not all respondents answered this question. The same was true in Iowa and Wisconsin. There was a higher negative response in Iowa where five out of twelve said they would not be interested in shipping to a facility at Savanna. The same reasons were given plus the necessity for paying a toll to cross the river to a terminal at Savanna. It should be noted that several of the "no" answers were qualified by such statements as, "If turnaround time is reduced, we would consider it," and, "If the elevator charges are attractive, we would be interested," and so forth.

Only one Wisconsin elevator responded to this question, and it was a "no" response. This respondent felt that the roads to Savanna were inadequate and traffic on them too slow, resulting in an increase in time to deliver and return. Several respondents also felt that weight limits on secondary route bridges and roads which they could use to reduce the turnaround time, were other limitations. Several elevator operators stated they would not be interested in a facility at Savanna. However, because of their qualifications and conditional answers, their marketings were included in the analysis of grain movement and transportation costs for the study area. Analysis of

survey results indicated that about 30 percent of all grain available for export in the study area would move through a Savanna terminal due to lower highway transport costs.

However, in consideration of the non-committal, negative and qualifying response to the question regarding use of a Savanna river terminal, and since a good portion of the grain estimated to move to Savanna due to lower trucking costs was based on marginal savings, survey data were re-examined and a conservative estimate of grain likely to be available for a Savanna facility was developed (table 9). This analysis indicated that a more realistic estimate of grain moving to Savanna due to lower transportation costs would be in the neighborhood of 11 to 14 million bushels of grain by 1980, rather than the 22 million bushels previously estimated based on unqualified savings in trucking costs. The 22 million bushel estimate was developed in strict adherence to transportation savings as the guiding principle in directing grain flow, regardless of how small the savings might be. In addition to ignoring changes in grain flow due to marginal truck transport savings, the more conservative estimates take into account that some grain now moving to nonriver terminal destinations, especially oats, would not likely be diverted to Savanna.

Table 9 shows three estimated levels of grain movement to a Savanna terminal based on savings in trucking costs and three different analyses and sets of assumptions relative to marginal savings and flow of grain to non-river destinations. Volumes of corn, soybeans, and oats expected to move to Savanna based on results of the 1975-76 marketing-year grain movement survey are shown for 1975 and projected to 1980, 1985, 1990 and 1995. Tables 1, 2, and 3 in Appendix A show the grain flow and transportation cost analysis in more detail.

## FINANCIAL FEASIBILITY

The financial feasibility of a river grain facility at Savanna, Illinois was evaluated using secondary data and assumptions regarding the facility's function. First hand information on size of facility, services to be performed, cost of plant, equipment, site preparation, land, financing, and expected charges for services rendered are needed before a realistic financial feasibility analysis can be made. However, one of the key variables in the analysis has been appraised--the demand for the facility in terms of exportable surplus grain in the proposed facility's service area. Exportable surplus grain is expected to increase over the next 15 years (tables 4, 5, and 6). Based on the grain flow and transportation cost analysis of moving grain from country elevators to river terminals, it appears that a facility at Savanna could favorably compete for a sizeable share of the area's exportable surplus grain in view of estimated savings in transportation costs to farmers and country elevator operators (tables 8 and 9). This conclusion is based solely on the transportation costs of moving grain from production sites in the port facility service area to existing river terminals and to a proposed river terminal at Savanna. It does not account for competitive response, such as existing firms' pricing policies and services offered, nor does it include assessments of barge availability, possible added cost of barging and quality of management of the new facility.

Since costs of operation will influence the price a Savanna river terminal can successfully bid for grain, a realistic appraisal of investment and operating costs must be made before financial feasibility can be assessed. To illustrate one approach in making the appraisal, a cost/return analysis was prepared for the proposed river port facility using three hypothetical models of river terminals and assumed costs and returns (tables 10, 11, 12, 13, 14 and 15). Estimated costs are based on fixed and variable costs of typical grain elevators as indicated by

Table 10—Annual operating costs for three hypothetical river subterminal grain elevator models of specified capacities, 1980 <sup>1/</sup>

Item	Model I 500,000 bushel capacity	Model II 1,000,000 bushel capacity	Model III 2,000,000 bushel capacity

(7) Present value of future stream of net revenue over 15-year debt repayment period at 9 percent interest rate		5,676,758	
(8) Ratio of present value of future net revenue to total investment cost <u>6/</u>			1.26

1/ Assumes equity capital (\$1,500,000) equivalent to one-third of total cost of grain port complex (\$4,500,000), or indebtedness of \$3,000,000.

2/ Based on elevator handling an annual estimated volume of grain of 13,710,500 bushels with an average handling margin of 12 cents per bushel. Average annual volume of grain based on estimate No. 3, table 9.

3/ 13,710,500 bushels x 12 cents per bushel port elevator handling margin less total annual operating expenses, assume to average \$941,000 per year over 15-year period, equal average net revenue of \$704,260 per year.

4/ Costs estimated from data in table 11. Variable costs were estimated to be \$524,000 annually at a handling volume of 13,710,500 bushels and fixed costs were unchanged at \$417,000.

5/ \$1,099,260 ÷ \$372,180.

6/ \$5,676,758 ÷ \$4,500,000.

Thurston (16), Schienbein and Vosloh (15) and "rule of thumb" construction cost estimates acquired via informal discussions with people in the grain elevator business and other studies on construction of grain terminal and port facilities. Cost data for the three models include an assumed cost for land, site preparation, a wharf, moorings, and on-site roads based on estimates from studies of port development on the Arkansas River. 6/

The estimated operating costs are based on functions the proposed river subterminal at Savanna is expected or assumed to perform and related facility and equipment requirements. It is assumed that the elevator will specialize in a fast throughput for loading barges with grain to be shipped to Gulf ports in the vicinity of Baton Rouge-New Orleans, Louisiana with possibly some intermediate destinations. It will, in addition to its main receiving and loadout function, provide drying and storage services. It is anticipated that the river elevator will receive most of its grain from country elevators, but some grain will come direct from farms and this grain may require drying and storage. Grain will be received predominantly from large trailer trucks in loads of 500 bushels or more. Storage facilities will be adequate to provide limited storage to local farmers and country elevators, and also allow grain collections sufficient to loadout one tow consisting of either twelve 175-foot hopper barges or six 195-foot hopper barges, requiring 12,000

6/ Tippetts-Abbett-McCarthy-Stratton, Engineers and Architects, Development of Marine Terminal Facilities, Pulaski County, Arkansas (Prepared for Little Rock Port Authority), New York, N.Y., October 1962; and Bovay Engineers, Inc., Grain Transfer Facility Study (Prepared for Ozarks Regional Commission and Little Rock Port Authority), Houston, Texas.

tons or 9,000 tons of grain respectively. 7/

A tow of twelve 175-foot barges would require about 429,000 bushels of corn to load it to capacity, and a fully-loaded tow of six 195-foot barges would require 321,000 bushels of corn. Elevator model I in table 10, the smallest of the three models, has a storage capacity of 500,000 bushels, enough to load about nine 195-foot hopper barges. Model II and model III could store enough grain to load 19 and 37 of the 195-foot barges, respectively. Storage capability may be important in acquiring barge service and in planning an efficient system of grain handling relative to loading barges and assembling barge tows. However, it is unlikely that the Savanna facility would ever loadout a complete tow at once. Barges are often hard to get and arrival is unpredictable. A tow is usually made up from several shippers. Nevertheless, storage could be critical for other reasons.

Storage could be important in attracting the business of local country elevators and farmers, especially during the harvest season, late fall and early spring, when both storage facilities and barges may be in short supply. The Upper Mississippi is closed by ice about 4 months of the year, from late December into April. Therefore, storage would be needed for all grain re-

---

7/ Hopper barges come in three standard lengths: 175, 195, and 290 feet with cargo holds of 1,000-, 1,500-, and 3,000-ton capacities. Some are open and some have waterproof covers. The two standard sizes of covered cargo barges are the 175-and 195-foot versions with the same dimensions and capacities as the 175-foot and 195-foot open-hopper barges. On the Upper Mississippi and Illinois Rivers, most locks are 110 feet wide and 600 feet long which allow single-time locking of tows of twelve 175-foot or six 195-foot barges. Larger tows are disassembled before and rejoined after locking, but this is expensive. Normally, more than 15 barges per tow is not considered good practice where a number of locks are involved. The average number of barges per tow has been estimated at between 20 and 30 on the Lower Mississippi and between 10 and 15 on the Upper Mississippi. The most popular covered barge for hauling grain is the 195-foot, 1,500-ton capacity size. It can haul as much grain as 25 conventional boxcars or 15 jumbo-hopper railcars. The 290-foot barge is used mostly south of St. Louis on the Mississippi where the river is open--free of locks and dams (6, 14).

received but not shipped out before the winter freeze, or received during the freeze.

Since storage may be a critical factor in the river elevators' success for the reasons just cited, the three models in table 10 include facilities for providing storage ranging from 500,000 bushels to 2 million bushels of grain. Also, since a prime objective of the elevator is to provide a fast throughput for barge loading, receiving and loading capacities are assumed to average between 20,000 and 30,000 bushels per hour. Drying capacity is expected to average between 3,000 and 5,000 bushels per hour. 8/ Including cost of land, port structures, site preparation, and roads, construction and equipment costs of model I are estimated at \$3 million; model II \$4.5 million; and model III, \$7 million.

Table 10 shows total annual operating costs and average annual costs per bushel for each of the three model elevators when the annual volume of grain handled is as indicated. Volumes handled are based on annual turnover rates of 4.5 for model I, and 7.0 for models II and III. 9/ Costs per bushel can vary sharply as the volume of grain handled changes. Average operating costs per bushel for elevator model II drop from 23.2 cents to 9.5 cents as annual volume increases from 3 million to 9 million bushels (table 11).

8/ Removing 5 percentage points of moisture.

9/ These annual turnover rates (ratio of grain volume handled during a year to storage capacity) were assumed reasonable for a river subterminal elevator. The turnover rate varies among types of elevators. It averaged 9.6 for U.S. port elevators in 1974 (17), and 2.52 for local farm cooperative elevators in Illinois in 1971-72 (12). Turnover rates ranged from about 3.0 to 9.0 for U.S. inland and port grain terminals, respectively, in 1971-72 (15). A turnover of about 7.0 is typical for a river elevator with a fast throughput for barge loading and facilities for storing about 1 million bushels of grain (16). Of course, the turnover rate is influenced by volume of grain business, amount of direct loading from incoming carrier to barge, extent of storage facilities, and type of storage. A river grain facility could specialize in barge loading services only and provide limited or no storage, thereby reducing investment costs. This alternative could be explored as a possible starting point for the proposed facility at Savanna.

A cost-return analysis was prepared for model II (tables 12, 13, 14, and 15), assuming that the proposed river subterminal at Savanna would approximate the grain-handling facilities and capability of this model. Three levels of grain business were assumed in making the analysis, reflecting varying degrees of conservatism regarding expected grain trade (table 9). Estimated returns on investment are 5, 10, and 16 percent, depending upon volume of grain handled (tables 12, 13, and 14). These rates of return are computed on the total cost of facilities, estimated at \$4.5 million; that is, the total amount of investment capital, including both borrowed funds and owners equity.

Table 15 presents the estimated present value (\$5,676,758) of the terminal's future net revenue and other financial data over an assumed 15-year debt retirement period. Annual cash flow is estimated at \$1,099,260 and the ratio of annual cash flow to annual debt service is 2.95. These estimates are based on the assumption that the proposed river terminal will handle at least 13,710,500 bushels of grain annually over the 15-year period, with an annual average revenue of 12 cents per bushel. This estimated volume appears to be a conservative and reasonable expectation based on estimates in table 9. The revenue estimates in table 12 are based on the assumption that a river elevator at Savanna will exercise the storage option and provide some grain storage for country elevators and farmers in the study area. If grain storage is not a revenue generating function of the Savanna terminal then results of the cost/return analysis would be considerably different, because cost of storage facilities storage revenue are important factors in the annual cost and return estimates used in the analysis.

The annual volume of grain assumed in this analysis appeared feasible in light of the estimated exportable surplus grain in the project area (tables 4, 5, and 6) and the indicated flow of grain from country dealers to a Savanna

river elevator based on the transportation cost analysis (tables 8 and 9). Carroll County (where the grain terminal is to be located) alone had an exportable surplus of corn estimated at about 6.2 million bushels in 1975, and this surplus is projected to average about 7.4 million bushels per year over the next 15 years (table 4). Exportable surpluses of soybeans and oats in Carroll County are expected to average a little over one-half million bushels each (tables 5 and 6). In addition to Carroll County, the Savanna facility should draw additional grain from neighboring counties which are projected to have increasing amounts of surplus grain and soybeans over the next 15 years (tables 4, 5, 6, 8, and 9).

The most conservative approach to the cost-return analysis was taken in table 12 where the annual volume of grain trade was estimated at 9 million bushels. This amounted to a 20 percent reduction in estimate No. 3 for 1980 (table 9) to account for the likelihood that during the first year of operation business may be difficult to generate in spite of savings in trucking costs and other incentives. Most of this grain could be expected to come from nearby locations in Carroll, Jo Daviess, and Western Stephenson and Ogle counties.

The annual returns in tables 12, 13, 14, and 15 assume an elevator bid price for grain adequate to cover barge transportation costs to Gulf ports and storage and handling costs of the grain elevator. The elevator will need to charge a port margin that will allow for all costs to be covered, including grain transportation costs from the facility to the Gulf (Baton Rouge-New Orleans). In the cost/return analysis, it was assumed that the model II elevator could acquire the indicated volume of grain via a terminal bid price that would cover barge transportation costs to the Gulf and provide an annual average operating margin of 12 cents per bushel. According

to estimated barge costs to the Gulf and recent spreads in Gulf bid prices and F.O.B. barge terminal prices on the upper Mississippi River 10/ the 12 cents per bushel river elevator handling margin appeared to be a reasonable, assumption.

Elevator operating costs and barge transportation costs estimated for the cost/return analysis appear to be reasonable, based on findings in other studies. However, an appraisal of the grain elevator cost structure and barge transportation charges in the area around Savanna, Illinois may prove these estimates to be either too low or too high.

A study of 14 midwestern grain cooperatives indicated an average cost of \$3.88 per ton for shipping grain to the Gulf in 1970. These barge shipments were centered in Illinois, Minnesota, Iowa, and Missouri (14). Adjusting the cost of \$3.88 per ton for price movements between 1970 and 1977, indicates a current adjusted average cost of \$6.83 per ton, or 19 cents per bushel, assuming the grain was all corn. Another study showed barge costs for a more specific location--Dubuque, Iowa. This study estimated 1974 costs of shipping corn by barge from Dubuque to the Gulf to be \$7.15 per ton (6). Adjusted for price movements, this would indicate a 1977 cost of \$8.67 per ton, or 24 cents per bushel for barging corn from Dubuque to the Gulf. Using this last study as a basis for approximating barge costs, it is estimated that average costs of shipping corn and soybeans by barge from Savanna, Illinois to Gulf ports will be about \$8.67 per ton, or 24.3 cents and 26.0 cents per bushel for corn and soybeans respectively. 11/

10/ C&MS, USDA, Summary of Daily Prices, Spot, F.O.B., Mississippi River Barge Terminal Elevators and Delivered Port, Gulf, 1978 and 1979.

11/ Current estimated costs are based on a 1974 cost of \$7.15 per ton for shipping corn by barge from Dubuque, Iowa to the Gulf (6) and expanding this cost estimate, using wholesale price movement between 1974 and 1977, to account for rising prices since 1974 ( $\$7.15 \times 1.213 = \$8.67$ ).

Barge rates for hauling exempt bulk commodities such as grain vary with demand for transportation services. Generally, barge rates are negotiated between shipper and carrier. Discounts below or premiums above a published rate depend upon how many barges are available and the need for them. Although actual barge operating costs vary depending upon origin and destination points, commodity hauled, and whether movement is upstream or downstream, effective barge rates in the short-run are more tied to the demand-supply situation than to hauling costs. Seasonality of grain harvests produce peak and off-peak periods of demand for barge service. Weather, volume of production, local storage and drying capacities, and export demand for grain modify the seasonal demand for transportation equipment. Normally, higher rates are charged during peak periods and decline into the off-seasons (6, 14).

Average current elevator receiving (by truck) and loadout (by water) costs per bushel for corn and soybeans are estimated at 5.5 cents and 5.3 cents (excluding storage costs), respectively, based on data in one grain transportation study. <sup>12/</sup> Based on another study, current average grain handling costs (all grains combined, excluding storage costs), when received by truck and loaded out by water, are estimated at 4.86 cents and 6.12 cents per bushel for inland terminals and port terminals, respectively. Using results in the same study, current costs of storage for one year would average about 23.4 cents and 36.3 cents per bushel for inland and port

---

<sup>12/</sup> Estimates are based on U.S. average 1971-72 costs per bushel of 2.022 cents per ton for corn and soybeans, respectively, (5), with adjustments for price increases between 1971 and 1977 using the Bureau of Labor Statistics' (BLS) Wholesale Price Index series.

terminals, respectively. <sup>13/</sup> Using the above range of costs as guidelines, and combining receiving and loadout costs with storage costs for two months (assuming grain shipped by barge is held, on the average, for about two months by the river subterminal) elevator operating costs per bushel of grain handled would average between 8.9 and 12.2 cents. These cost estimates are reasonably close to those in tables 10 and 11.

Of course, operating costs can vary considerably depending upon the size of investment in facilities and the annual volume handled. For the sample of grain elevators on which the basic cost data above were developed, storage capacity and annual volume handled averaged about 7 million bushels and 21 million bushels, respectively, for inland terminals, and 5.2 million bushels and 47 million bushels, respectively, for port terminals (15).

When a clearer picture is obtained of site location and services expected to be provided by the proposed river grain facility at Savanna, annual costs can be better estimated by obtaining bids on installation costs from river port and grain elevator construction contractors and equipment dealers. These should include costs of site preparation such as dredging, piers, and access roads, as well as costs of equipment and buildings. The estimated costs in tables 10 through 15 can then be adjusted to reflect these more solid cost figures.

---

<sup>13/</sup> Estimates are based on U.S. average 1971-72 costs per bushel of 2.022 cents for receiving grain by truck and 0.831 cents for loading out by water for inland terminals, and 2.512 cents for receiving by truck and 1.075 cents for loading out by water for port terminals (15)--all adjusted for price movements between 1971 and 1977 using the Wholesale Price Index of BLS. Estimates of storage costs are based on 1971-72 U.S. average costs of 13.745 cents and 21.348 cents per bushel for inland and port terminals, respectively (15), adjusted to reflect current prices.

AN OVERVIEW OF THE GRAIN EXPORT MARKET AND TRANSPORTATION PROBLEMS  
FACING UPPER MISSISSIPPI RIVER BARGE TERMINALS

Major U. S. agricultural commodities moving in world trade are corn, wheat, and soybeans. The world market for U. S. corn and soybeans is expected to remain strong with exports estimated to remain at somewhat above the export levels established in the seventies. High and low level projections of U. S. feedgrain exports in 1985 are estimated at 55 million and 35 million tons (corn normally accounts for about four-fifths of the total feedgrain exports). Estimated 1985 export projections for soybeans range from a high of 28 million tons to a low of 25 million tons. 14/ The 1985 high-level export estimate for feedgrains is 60 percent above the 1975 exports, and the 1985 high-level export estimate for soybeans is about two and one-half times the 1975 quantity exported (17, 21).

Shipments of corn, wheat, and soybeans through Gulf ports accounted for more than two-thirds of the corn, over one-half of the wheat, and about four-fifths of the soybean exports in 1974. The Mississippi and Illinois Rivers are the principal inland waterways for barging grains. In 1974, nearly two-thirds of the grain shipments originating on the Upper Mississippi (north of St. Louis) was transported to the Baton Rouge-New Orleans, Louisiana area. The Louisiana Gulf ports take in almost all the barge-shipped soybeans and corn, and most of it comes from the Mid-West (north of St. Louis) barge terminals on the Mississippi and Illinois Rivers. For example, in 1974, about 14.6 million tons of corn and 4.4 million tons of soybeans were shipped to Louisiana Gulf ports, down the Mississippi from areas north of St. Louis. This accounted for about 88 percent of the corn and 53 percent of the soybeans moved by barge that year to various domestic and export ports in the United States (6, 20).

14/ These tonnage figures are in metric tons. To convert to U. S. short tons, multiply metric tons by 1.1023. A metric ton is equal to 2,204.622 pounds the short ton, 2,000 pounds.

Surplus corn and soybean production in the 11-county grain service market area of the proposed Savanna grain subterminal is projected to increase over the next 17 years, creating a need for more grain transportation service. Corn and soybeans shipped to river grain terminals on the Illinois and Mississippi Rivers normally goes to Louisiana Gulf ports for export. Therefore, considering the favorable prospects for future exports, it would appear that the 11-county area around Savanna should continue to enjoy a share of the grain export market, given adequate marketing and transportation facilities.

A new river terminal located at Savanna, according to an analysis of the results of the transportation study (tables 7, 8, and 9), could capture a share of the export trade in the range of 11.3 to 22.2 million bushels annually by 1980, assuming that savings in highway transport costs alone could attract grain movement to the new facility.

However, if the export market should decline, it could have a very depressing effect on the grain terminal business and revenues. Unexpected interruption of the cash flow of a new terminal along the Mississippi River could be critical. Also, damage and/or deterioration in lock and dam facilities could hamper trade of grain terminals along the Mississippi. Locks and Dam 26, at Alton, Illinois, is a case in point. It is estimated by the Corps of Engineers that the locks will reach maximum capacity of 73 million tons a year by 1982. The current annual rate of traffic is about 50 million tons (20).

Another item of consideration for a barge terminal is the effect of waterway user charges on its business. One study of the possible effects of waterway user charges on grain and fertilizer shipments indicated that charges of 0.05 cents or less per ton mile would have no effect on barge shipments of grain. At 0.10 cents per ton mile barge shipments of grain decreased by 29 percent, and at 0.25 cents per ton mile, no grain was shipped by barge (4). Although this study was done for only one county in central Illinois, near barge loading points on the Illinois River, it could have valuable implications for other barge shipping areas, depending upon local alternative transportation services (rail or truck).

## CONCLUSIONS

The conclusions drawn from this study are:

1. There is a sufficient volume of grain production and exportable surplus presently available in the 11-county survey area to support an efficient sized river grain terminal marketing facility at Savanna, Illinois. In the 1975-76 marketing year, there were 24.6 million bushels available for export from 45 shippers. Transportation analysis relative to grain flows and costs of highway transport indicated that 20 million bushels of this exportable surplus would have moved to a Savanna terminal in 1975, and 22 million by 1980. These estimates are based on analysis of highway transport costs alone and include some grain movement to Savanna based on marginal savings in highway shipping costs.

In analyzing the location of survey respondents, it is believed that the 20 million bushels of grain indicated going to Savanna in 1975 is on the high side. A somewhat conservative and more reasonable estimate of what a Savanna terminal might have expected, based on highway transport savings of moving grain from farms and country elevators to terminals, would have been about 11 to 14 million bushels of grain in the 1975-76 marketing year.

2. The volume of production of corn and soybeans is trending upward and this trend should continue but at a slower rate in the future (projected to 1995), unless there is an unexpected increase in average yields. Oat production is trending downward and this trend should continue but at a slow rate when projected to 1995.
3. The volume of exportable surplus of soybeans and corn is trending upward but should slow down in the future, projected to 1995. Exportable surplus of oats is projected to decline in the future.

4. Corn is the major grain for export in the proposed grain terminal service area. Of the total exportable surplus grain, corn accounts for 84 percent. The estimated exportable surplus of corn is projected to increase from 58.3 million to 86.7 million bushels between 1975 and 1995, which is an average increase of 1.4 million bushels per year during the 20-year period.
5. The predominant mode of grain transport to river terminals was by trucks hauling 500 bushels or more. The cost of transporting corn and oats was .096 cents per bushel per mile, and soybeans .086 cents per bushel per mile in 1975-76.
6. The estimated benefits to shippers and farmers resulting from savings in cost of highway transportation by the 45 survey respondents in the 1975-76 marketing year, had they shipped their corn, soybeans, and oats to Savanna rather than the terminals to which they did ship, is \$594,000. This estimate is a little high because it includes diverting some grain to Savanna from non-river destinations, which is unlikely, and some grain being moved to Savanna based on very marginal transport savings.
7. Study results based on highway transport costs alone, indicate that a grain terminal at Savanna might expect the following volume of grain business over the next 15 years: 11 to 14 million bushels by 1980; 12 to 15 million bushels by 1985; 15 to 18 million bushels by 1990; and 17 to 20 million bushels by 1995.
8. Results of the cost/return analysis indicate an investment yield ranging from 5 to 16 percent based on projected variable grain handling volumes at a river grain terminal at Savanna. Results were based on cost estimates and revenues that could vary considerably

from those arising from a more thorough examination of costs and returns by the local RC&D sponsors. Once the sponsors decide exactly where on the river the terminal is to be located, and acquire solid figures on site preparation and cost of facilities from construction contractors and grain equipment dealers, and determine barge costs to the Gulf, they can revise the cost/return analysis using the estimated expected grain movement to Savanna as an approximation of grain business in planning the size of their operation. The Savanna terminal probably should start out small in terms of total investment, plan for a fast throughput operation, and allow for expansion of operations and services as experience dictates.

The estimates of grain movement to Savanna are based on limiting assumptions and, therefore, should be interpreted cautiously and used only as general planning guidelines. There is no assurance that the grain will move to Savanna based on savings in trucking costs alone, but this does give the local RC&D sponsors of the proposed grain facility a starting point for making investment/development decisions.

<sup>1/</sup> Terminal code indicates destination of grain shipped by survey respondent country elevators and trucker-dealers located in cities shown in column 1. Terminal codes are as follow: A = Albany; C = Clinton; H = Hennepin; SV = Spring Valley; O = Ottawa; CH = Chicago; DU = Dubuque; DP = Davenport; CR = Cedar Rapids; G = Galesburg; K = Keokuk; LS = LaSalle; and M = Mendota.

<sup>2/</sup> Indicated savings per bushel is obtained by multiplying the "miles saved" by the survey indicated hauling costs: .096 cents per bushel per mile for corn and oats, and .086 cents per bushel per mile for soybeans. Savings in trucking costs per bushel times volume shipped equals net transportation savings to shippers.

BLACKHAWK HILLS RC&D RIVER PORT GRAIN  
FACILITY COMMITTEECountry Elevator Survey

Name of Firm \_\_\_\_\_ Date \_\_\_\_\_  
Town \_\_\_\_\_ Street \_\_\_\_\_ Phone \_\_\_\_\_  
County \_\_\_\_\_ Township \_\_\_\_\_ State \_\_\_\_\_

1. Current storage capacity: \_\_\_\_\_ bushels
2. Volume of grain handled (Sept. 1, 1975 to Sept. 1, 1976):
  - a. Corn \_\_\_\_\_ bushels
  - b. Oats \_\_\_\_\_ bushels
  - c. Wheat \_\_\_\_\_ bushels
  - d. Soybeans \_\_\_\_\_ bushels
  - TOTAL \_\_\_\_\_ bushels
3. What portion of the grains that you handled through your elevator went to local feed mills, back to the farm as whole grain, or as feed milled by you? (Please estimate as closely as possible.)
  - a. Corn \_\_\_\_\_ % or \_\_\_\_\_ bushels
  - b. Oats \_\_\_\_\_ % or \_\_\_\_\_ bushels
  - c. Wheat \_\_\_\_\_ % or \_\_\_\_\_ bushels
  - d. Soybeans \_\_\_\_\_ % or \_\_\_\_\_ bushels

Please answer the questions on the following pages for each of the grain crops handled through your elevator during the 1975-76 marketing year. (CORN page 2, OATS page 3, WHEAT page 4, and SOYBEANS page 5)

CORN

4. If you marketed CORN to another marketing facility (other than a local feed mill or back to the farm) what percent was transported by: (Fill out as many of the modes as you used to transport corn.)
- a. Truck (300 to 500 bu.) \_\_\_\_\_ %      d. Rail (2 to 10 cars) \_\_\_\_\_ %  
b. Truck (over 500 bu.) \_\_\_\_\_ %      e. Rail (over 10 cars) \_\_\_\_\_ %  
c. Rail (single car) \_\_\_\_\_ %      f. Other (explain) \_\_\_\_\_ %
5. What was the average cost for moving the CORN in the 1975-76 marketing year by:  
(Report cost in cents per bu. or dollars per ton per mile in appropriate blanks.)
- a. Truck  
(300-500 bu.) \_\_\_\_\_ Cents/bu/mile  
                        \_\_\_\_\_ Dollars/ton/mile
- b. Truck  
(over 500 bu.) \_\_\_\_\_ Cents/bu/mile  
                        \_\_\_\_\_ Dollars/ton/mile
- c. Rail  
(single car) \_\_\_\_\_ Cents/bu/mile  
                        \_\_\_\_\_ Dollars/ton/mile
- d. Rail  
(2 to 10 cars) \_\_\_\_\_ Cents/bu/mile  
                        \_\_\_\_\_ Dollars/ton/mile
- e. Rail  
(over 10 cars) \_\_\_\_\_ Cents/bu/mile  
                        \_\_\_\_\_ Dollars/ton/mile
- f. Other (explain) \_\_\_\_\_ Cents/bu/mile  
                        \_\_\_\_\_ Dollars/ton/mile
6. Where did the CORN you moved from your elevator go, other than to local feed mills or back to the farm?
